## Bacterial Death

Death of any living organism can be defined as an **irreversible inactivation** of it, so it does not **grow** nor **reproduce** anymore.

### To confirm the death of bacteria:

We grow it on a **suitable media** (*agar plate for example*) and see if it **forms colonies** or **not** so then we can confirm whether the bacteria is **alive or dead** originally.

**Note:** The setup (media) must be of **suitable conditions** to the bacteria we are studying, because if it wasn't suitable the bacteria would be **dead** and we won't know if it was originally dead or not.

### Exponential decrease through bacterial death

As seen in the following graph, An exponential decrease in microbial survivors takes place and varies in degree according to **the killing agent**.

The **rate** of bacteria death is **90%** per every **minute**.

**Note:** The curve is **not linear** because at some point the bacteria will **adapt** to the conditions applied by the killing agent.

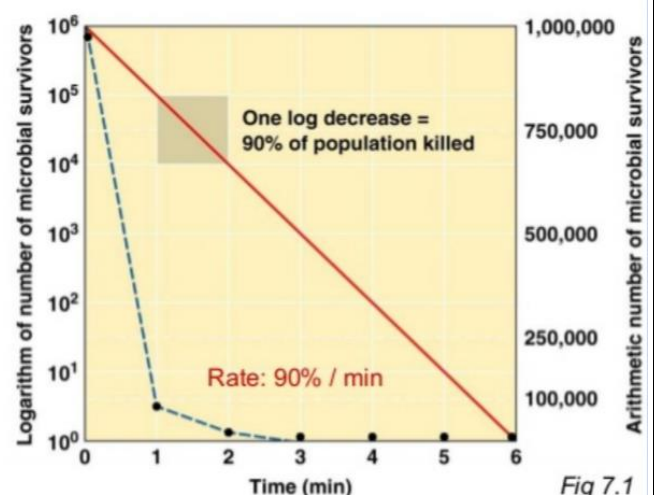

Fig 7.1

### Formula of cell death

$$S = S_0 * e^{-kt}$$

**S** → Number of cells **survived after** using a killing agent

**S<sup>0</sup>** → Number of cells **originally**

**E** → Depends on the **type of the killing agent**

## Antimicrobial Agents Definitions

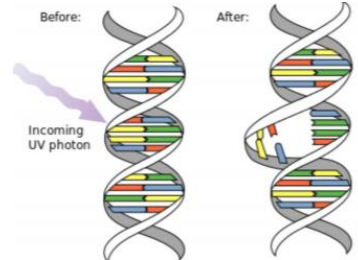

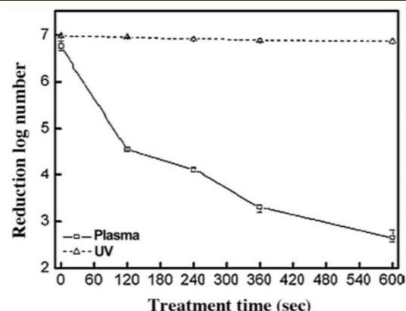

1	<b>Sterilization</b>	A process to make an object <b>free from any living organism</b> on a surface.
2	<b>Disinfection</b>	Removal of <b>some microorganism</b> to get a surface that is appropriate to <b>use level</b> . It is <b>less effective</b> than sterilization. <i><b>Note:</b> Some microorganisms <b>may persists</b> since they are <b>highly resistant</b> microbes like <b>spores</b> and <b>prions</b>.</i>
3	<b>Cleaning</b>	Removal of <b>organic and inorganic materials</b> ( <i>biofilm</i> ) from objects mechanically with <b>water</b> or <b>fire</b> for example.

**Bacteriostatic:** It is the **reversible inactivating** of an organism process.  
*Once we remove the agent the bacteria will **resume** its growth and replication.*

**Bactericidal:** It is the **irreversible inactivating** of an organism process.  
*Even if we **remove** the agent the bacteria will still be **dead**.*

## Sterilization Processes

1	Autoclaves	<p>They are <b>strong containers</b> that use <b>pressurized</b> and <b>saturated steams</b> at almost 121 C° for around 15-20 min.</p> <p>It's the most <b>efficient</b> way to kill microorganism using <b>heat</b> and <b>pressure</b>.</p>																																					
2	Filters	With <b>pores</b> size of <b>0.2 μm</b> filters mostly, microorganisms will be <b>retained</b> .																																					
3	Chemicals	<p><b>Hydrogen peroxide</b> is used in high concentrations (10%-30%). <b>Glutaraldehyde</b> is used with long contact times (3-12hr).</p> <p><b>Note:</b> Both when used at <b>lower concentration/time</b> may be considered <b>disinfectants</b> since they wont be as <b>effective</b> to be <b>considered</b> sterilizing agents.</p>																																					
4	Radiations	<p><b>UV radiation</b> damages DNA by <b>crosslinking adjacent</b> pyrimidines.</p> <p><b>Ionizing radiation</b> like <b>Gamma radiation</b> for example causes <b>strand breaks</b></p> <p><b>Note:</b> Gamma radiation has <b>better penetration into materials</b> than UV radiations.</p>																																					
5	Gas plasma /Vapor phase	<p>This process shows <b>high efficiency</b> in killing <b>spores</b>.</p> <p><b>Example:</b> Hydrogen peroxide and Peracetic acid in <b>vapor form</b></p> <p>The graph shows that <b>Plasma</b> kills bacteria <b>better</b> than <b>UV</b></p>	 <table><caption>Approximate data from the graph</caption><thead><tr><th>Treatment time (sec)</th><th>Plasma (Reduction log number)</th><th>UV (Reduction log number)</th></tr></thead><tbody><tr><td>0</td><td>7.0</td><td>7.0</td></tr><tr><td>60</td><td>6.5</td><td>7.0</td></tr><tr><td>120</td><td>4.5</td><td>7.0</td></tr><tr><td>180</td><td>4.2</td><td>7.0</td></tr><tr><td>240</td><td>4.0</td><td>7.0</td></tr><tr><td>300</td><td>3.8</td><td>7.0</td></tr><tr><td>360</td><td>3.5</td><td>7.0</td></tr><tr><td>420</td><td>3.3</td><td>7.0</td></tr><tr><td>480</td><td>3.1</td><td>7.0</td></tr><tr><td>540</td><td>2.9</td><td>7.0</td></tr><tr><td>600</td><td>2.7</td><td>7.0</td></tr></tbody></table>	Treatment time (sec)	Plasma (Reduction log number)	UV (Reduction log number)	0	7.0	7.0	60	6.5	7.0	120	4.5	7.0	180	4.2	7.0	240	4.0	7.0	300	3.8	7.0	360	3.5	7.0	420	3.3	7.0	480	3.1	7.0	540	2.9	7.0	600	2.7	7.0
Treatment time (sec)	Plasma (Reduction log number)	UV (Reduction log number)																																					
0	7.0	7.0																																					
60	6.5	7.0																																					
120	4.5	7.0																																					
180	4.2	7.0																																					
240	4.0	7.0																																					
300	3.8	7.0																																					
360	3.5	7.0																																					
420	3.3	7.0																																					
480	3.1	7.0																																					
540	2.9	7.0																																					
600	2.7	7.0																																					

**Note:** Sterilization processes are used **depending on the objects' nature**, for example some objects' are **heat sensitive** therefore we cannot use **autoclaves**, so filters or gas plasma are considered **more suitable**.

## Factors that affect efficacy of both disinfection and sterilization:

### 1) Prior cleaning

The presence of **biofilm** makes it harder for sterilizing agents and disinfectants to **penetrate** the bacteria and even sometimes **inactivates** the agents, so we have to **clean** the object before sterilizing/disinfecting to get rid of biofilms, that's why cleaning is **important**.

### 2) Organic and inorganic load present

This **decreases** the **efficacy of action** for both disinfection and sterilization.

### 3) Type and level of microbial contaminations.

Example: Prions, whom are **highly resistant**.

### 4) Concentration of and exposure time to the germicide (*killing agent*) as discussed before.

### 5) Physical nature of objects

If they have **crevices, hinges or lumens**, its hard to **reach** them properly.

### 6) Presence of biofilm

### 7) Temperature and pH of the disinfection process

## Antimicrobial Agents Definitions part 2

1	Septic	<p>Is the presence of <b>pathogenic microbes</b> in <b>living tissues</b> or <b>associated fluids</b>.</p> <p><b>Note:</b> A <b>septic shock</b> is a serious medical condition that occurs when <b>living tissues</b> are <b>damaged</b> in response to <b>infection</b> by <b>microbes</b>.</p>
2	Antiseptic	<p><b>Destroys or inhibits</b> the <b>growth</b> of microorganisms in or on <b>living tissues</b> or fluids. They are similar to disinfectants, but they work on <b>living tissues</b> unlike disinfectants.</p> <p><b>Example:</b> Alcohol, Iodine and Chlorhexidine.</p> 
3	Aseptic	<p>Is an adjective describing a <b>technique free of microorganisms</b></p> <p><b>Example:</b> Surgery</p>
4	Preservation	<p>Is the <b>prevention</b> of multiplication of microorganisms in formulated products using <b>preservatives</b>.</p>

## Mechanism of action of antimicrobial agents

### 1) Denaturation of proteins

Heat destroys the **tertiary structure** which gives a protein its **function**.

### 2) Oxidation damage interferes with **most biological processes** of the cell (membrane/DNA synthesis)

**Example:** Hydrogen peroxide interferes with **some enzymes** causing **biological** interferences.

### 3) DNA damage

**Example:** UV and Ionizing radiation.

### 4) Cell membrane and cell wall disruption

**Example:** Alcohol dissolves membrane lipids.

**This table is only for further explanation of how each Antimicrobial agent affect different microorganism and others**

Agents	Bacteria	Mycobacteria	Bacterial Spores	Fungi	Viruses
<b>Disinfectants</b>					
Alcohol	+	+	–	+	+/-
Hydrogen peroxide	+	+	+/-	+	+
Phenolics	+	+	–	+	+/-
Chlorine	+	+	+/-	+	+
Iodophors	+	+/-	–	+	+
Glutaraldehyde	+	+	+	+	+
Quaternary ammonium compounds	+/-	–	–	+/-	+/-
<b>Antiseptic Agents</b>					
Alcohol	+	+	–	+	+
Iodophors	+	+	–	+	+
Chlorhexidine	+	+	–	+	+
Parachlorometaxlenol	+/-	+/-	–	+	+/-
Triclosan	+	+/-	–	+/-	+

**+** → The microbe is **killed**

**–** → The microbe is **not killed**

**+/-** → Means that the effect **depends** on the **concentrations/time** used.

**Good Luck ☺**
